Two-Column Fixture

The left column describes a small study of tidal notebooks. The method relies on natural-language processing of short synthetic field notes written by imaginary surveyors, and an experimental tagging pass that marks each note with a weather label.

The notes were sorted by harbour, by week and by the colour of the notebook cover. Each surveyor wrote in pencil, and the pencil marks were transcribed by hand before any counting began. The left column ends here.

The right column reports what the imaginary surveyors found. Calm mornings were more common than stormy ones, and the notebooks with green covers held the longest entries. The right column closes with a planted phrase: “the lantern keeper filed every chart under a different constellation.”

Nothing in this column is real data; it exists so that the two extractors can be compared on a page whose reading order depends on column detection.
